# ERROR ANALYSIS AND COMPUTATIONAL ASPECTS OF SR FACTORIZATION VIA OPTIMAL SYMPLECTIC HOUSEHOLDER TRANSFORMATIONS* 

A. SALAM ${ }^{\dagger}$ AND E. AL-AIDAROUS ${ }^{\ddagger}$<br>Dedicated to Gérard Meurant on the occasion of his 60th birthday

#### Abstract

Symplectic QR like methods for solving some structured eigenvalue problems involves SR factorization as a key step. The optimal symplectic Householder SR factorization (SROSH algorithm) is a suitable choice for performing such a factorization. In this paper, we carry out a detailed error analysis of the SROSH algorithm. In particular, backward and forward error results are derived. Also, the computational aspects of the algorithm (such as storage, complexity, implementation, factored form, block representation) are described. Some numerical experiments are presented.

Key words. Skew-symmetric inner product, optimal symplectic Householder transformations, SR factorization, error analysis, backward and forward errors, implementation, factored form, WY factorization, complexity.

AMS subject classifications. 65F15, 65F50

1. Introduction. Let $A$ be a $2 n$-by- $2 n$ real matrix. The SR factorization consists in writing $A$ as the product $S R$, where $S$ is symplectic and $R$ is $J$-upper triangular, i.e.,

$$
R=\left[\begin{array}{ll}
R_{11} & R_{12} \\
R_{21} & R_{22}
\end{array}\right]
$$

is such that $R_{11}, R_{12}, R_{22}$ are upper triangular and $R_{21}$ is strictly upper triangular [3, 4]. This decomposition is a key step in constructing symplectic QR-like methods in order to solve the eigenvalue problem of a class of structured matrices; see [3, 9, 14]. It can be viewed as the equivalent of the classical QR factorization, when instead of an Euclidean space, one considers a linear space equipped with a specified skew-symmetric inner product; see $[8,12]$ and the references therein. The space is then called symplectic, and its orthogonal group with respect to this inner product is called the symplectic group. In contrast with the Euclidean case, the symplectic group is not compact. A numerical determination of the canonical form for symplectic matrices has been derived by Godunov et al. [5]. The set of real $2 n$-by- $2 n$ matrices for which a SR factorization exists is dense in $\mathbb{R}^{2 n \times 2 n}$ [3].

Computing the QR factorization is currently handled by the Gram-Schmidt orthogonalization process [1, 2] or via Householder transformations [6, 10, 15]. In the symplectic case, the SR factorization can be performed via symplectic Gram-Schmidt (SGS) algorithms (see [12] and the references therein) or by using the SRDECO algorithm [3]. Recently, a new algorithm (SROSH) for computing the SR factorization was proposed in [13]. It is a method based on optimal symplectic Householder transformations. We present here a detailed error analysis of the method. In particular, backward and forward error results are derived. Questions about how close is the computed symplectic factor to being symplectic and how large is the error in the SR factorization are answered. We also describe its most important computational aspects: storage, complexity, implementation, factored form, block representation.

[^0]The remainder of this paper is organized as follows. In Section 2, the symplectic Householder SR factorization is reviewed. Section 3 is devoted to the computational aspects of the optimal symplectic Householder SR factorization. Section 4 treats in detail the error analysis of the SROSH algorithm. Some illustrative numerical experiments are presented.
2. SR decomposition. We review briefly the SR factorization, via symplectic Householder transformations. A detailed study is provided in [13].
2.1. Symplectic Householder transformations (SHT). Let $J_{2 n}$ (or simply $J$ ) be the $2 n$-by- $2 n$ real matrix

$$
J_{2 n}=\left[\begin{array}{cc}
0_{n} & I_{n}  \tag{2.1}\\
-I_{n} & 0_{n}
\end{array}\right]
$$

where $0_{n}$ and $I_{n}$ stand for the $n$-by- $n$ null and identity matrices, resectively. The linear space $\mathbb{R}^{2 n}$ with the indefinite skew-symmetric inner product

$$
\begin{equation*}
(x, y)_{J}=x^{T} J y \tag{2.2}
\end{equation*}
$$

is called symplectic. We denote the orthogonality with respect to $(\cdot, \cdot)_{J}$ by $\perp^{\prime}$, i.e., for $x, y \in \mathbb{R}^{2 n}, x \perp^{\prime} y$ stands for $(x, y)_{J}=0$. The symplectic adjoint $x^{J}$ of a vector $x$ is defined by

$$
\begin{equation*}
x^{J}=x^{T} J \tag{2.3}
\end{equation*}
$$

The symplectic adjoint of $M \in \mathbb{R}^{2 n \times 2 k}$ is defined by

$$
\begin{equation*}
M^{J}=J_{2 k}^{T} M^{T} J_{2 n} \tag{2.4}
\end{equation*}
$$

Definition 2.1. A matrix $S \in \mathbb{R}^{2 n \times 2 k}$ is called symplectic if

$$
\begin{equation*}
S^{J} S=I_{2 k} \tag{2.5}
\end{equation*}
$$

The symplectic group (multiplicative group of square symplectic matrices) is denoted by $\mathbb{S}$. A transformation $T$ given by

$$
\begin{equation*}
T=I+c v v^{J} \text { where } c \in \mathbb{R}, \quad v \in \mathbb{R}^{\nu} \quad \text { (with } \nu \text { even) } \tag{2.6}
\end{equation*}
$$

is called a symplectic Householder transformation [13]. It satisfies

$$
\begin{equation*}
T^{J}=I-c v v^{J} \tag{2.7}
\end{equation*}
$$

The vector $v$ is called the direction of $T$.
2.2. The mapping problem. For $x, y \in \mathbb{R}^{n}$, there exists a symplectic Householder transformation $T$ such that $T x=y$ if $x=y$ or $x^{J} y \neq 0 . T$ is given by

$$
T=I-\frac{1}{x^{J} y}(y-x)(y-x)^{J}
$$

Moreover, each non-null vector $x$ can be mapped onto any non-null vector $y$ by a product of at most two symplectic Householder transformations. Symplectic Householder transformations are rotations, i.e., $\operatorname{det}(T)=1$; and the symplectic group $\mathbb{S}$ is generated by symplectic Householder transformations.
2.3. SR factorization via symplectic Householder transformations. The symplectic Householder SR factorization can be viewed as the analogue of Householder QR factorization in the symplectic case; see [13] for more details. Let $\left\{e_{1}, \ldots, e_{2 n}\right\}$ be the canonical basis of $\mathbb{R}^{2 n \times 2},[a, b] \in \mathbb{R}^{2 n \times 2}$, and $\rho, \mu$, and $\nu$ be arbitrary scalars. We seek symplectic Householder transformations $T_{1}$ and $T_{2}$ such that

$$
\begin{equation*}
T_{1}(a)=\rho e_{1}, \quad T_{2}\left(e_{1}\right)=e_{1}, \quad T_{2}\left(T_{1}(b)\right)=\mu e_{1}+\nu e_{n+1} \tag{2.8}
\end{equation*}
$$

The fact that $T_{2} T_{1}$ is a symplectic isometry yields the necessary condition

$$
\begin{equation*}
a^{J} b=\left(T_{2} T_{1}(a)\right)^{J}\left(T_{2} T_{1}(b)\right)=\rho \nu \tag{2.9}
\end{equation*}
$$

THEOREM 2.2. Let $\rho$, $\nu$ be such that (2.9) is satisfied, and let

$$
\begin{array}{ll}
c_{1}=-\frac{1}{\rho a^{J} e_{1}}, & v_{1}=\rho e_{1}-a \\
c_{2}=-\frac{1}{\left(T_{1}(b)\right)^{J}\left(\mu e_{1}+\nu e_{n+1}\right)}, & v_{2}=\mu e_{1}+\nu e_{n+1}-T_{1}(b)
\end{array}
$$

Then

$$
\begin{equation*}
T_{1}=I+c_{1} v_{1} v_{1}^{J}, \quad T_{2}=I+c_{2} v_{2} v_{2}^{J} \tag{2.10}
\end{equation*}
$$

satisfy (2.8).
2.4. The SRSH algorithm. We outline here the steps of the algorithm. Let $A=\left[a_{1}, \ldots, a_{p}, a_{p+1}, \ldots, a_{2 p}\right] \in \mathbb{R}^{2 n \times 2 p}$. Let $r_{11}, r_{1, p+1}, r_{p+1, p+1}$ be arbitrary scalars satisfying $r_{11} r_{p+1, p+1}=a_{1}^{J} a_{p+1}$. The first step of the SRSH algorithm is to find $T_{1}$ (i.e., $c_{1}$ and $v_{1}$ by Theorem 2.2) such that $T_{1}\left(a_{1}\right)=r_{11} e_{1}$ and $T_{2}$ (i.e., $c_{2}$ and $v_{2}$ by Theorem 2.2) such that $T_{2}\left(e_{1}\right)=e_{1}$ and $T_{2} T_{1}\left(a_{p+1}\right)=r_{1, p+1} e_{1}+r_{p+1, p+1} e_{n+1}$. This step involves two free parameters. The action of $T_{2} T_{1}$ on $A$ is

$$
T_{2} T_{1} A=\left[\begin{array}{cccc}
r_{11} & r(1,2: p) & r_{1, p+1} & r(1, p+2: 2 p) \\
0 & A_{11}^{(2)} & 0 & A_{12}^{(2)} \\
0 & r(p+1,2: p) & r_{p+1, p+1} & r(p+1, p+2: 2 p) \\
0 & A_{21}^{(2)} & 0 & A_{22}^{(2)}
\end{array}\right]
$$

Denote

$$
\tilde{A}^{(2)}=\left[\begin{array}{ll}
A_{11}^{(2)} & A_{12}^{(2)} \\
A_{21}^{(2)} & A_{22}^{(2)}
\end{array}\right],
$$

and let $r_{22}, r_{2, p+2}, r_{p+2, p+2}$ be arbitrary scalars with $\tilde{A}^{(2)}(1,:)^{J} \tilde{A}^{(2)}(p,:)=r_{22} r_{p+2, p+2}$. The next step is to apply the previous step to $\tilde{A}^{(2)}$, i.e., find (by Theorem 2.2)

$$
\begin{aligned}
& \tilde{T}_{3}=I_{2 n-2}+c_{3} \tilde{v}_{3} \tilde{v}_{3}^{J}, \text { where } \tilde{v}_{3}=\left[\frac{u_{3}}{w_{3}}\right] \in \mathbb{R}^{2 n-2}, \text { and } \\
& \tilde{T}_{4}=I_{2 n-2}+c_{4} \tilde{v}_{4} \tilde{v}_{4}^{J}, \text { where } \tilde{v}_{4}=\left[\frac{u_{4}}{w_{4}}\right] \in \mathbb{R}^{2 n-2},
\end{aligned}
$$

such that

$$
\tilde{T}_{4} \tilde{T}_{3} \tilde{A}^{(2)}=\left[\begin{array}{cccc}
r_{22} & r(2,3: p) & r_{2, p+2} & r(2, p+3: 2 p) \\
0 & A_{11}^{(3)} & 0 & A_{12}^{(3)} \\
0 & r(p+2,3: p) & r_{p+2, p+2} & r(p+2, p+3: 2 p) \\
0 & A_{21}^{(3)} & 0 & A_{22}^{(3)}
\end{array}\right]
$$

Set $T_{3}=I_{2 n}+c_{3} v_{3} v_{3}{ }^{J}, T_{4}=I_{2 n}+c_{4} v_{4} v_{4}{ }^{J}$, where

$$
\left[\begin{array}{ll}
v_{3} & v_{4}
\end{array}\right]=\left[\begin{array}{cc}
0 & 0 \\
u_{3} & u_{4} \\
\hline 0 & 0 \\
w_{3} & w_{4}
\end{array}\right] \in \mathbb{R}^{2 n \times 2}
$$

Then $T_{3}, T_{4}$ are symplectic Householder transformations [13], and their action is given by
$T_{4} T_{3} T_{2} T_{1} A=\left[\begin{array}{cccccc}r_{11} & r_{12} & r(1,3: p) & r_{1, p+1} & r_{1, p+2} & r(1, p+3: 2 p) \\ 0 & r_{22} & r(2,3: p) & 0 & r_{2, p+2} & r(2, p+3: 2 p) \\ 0 & 0 & A_{11}^{(3)} & 0 & 0 & A_{12}^{(3)} \\ 0 & r_{p+1,2} & r(p+1,3: p) & r_{p+1, p+1} & r_{p+1, p+2} & r(p+1, p+3: 2 p) \\ 0 & 0 & r(p+2,3: p) & 0 & r_{p+2, p+2} & r(p+2, p+3: 2 p) \\ 0 & 0 & A_{21}^{(3)} & 0 & 0 & A_{22}^{(3)}\end{array}\right]$.
The $j$ th step is now clear. At the last step ( $p$ th step), we obtain

$$
T_{2 p} T_{2 p-1} \ldots T_{4} T_{3} T_{2} T_{1} A=\left[\begin{array}{ll}
R_{11} & R_{12} \\
R_{21} & R_{22}
\end{array}\right]=R \in \mathbb{R}^{2 n \times 2 p}
$$

where $R_{11}, R_{12}, R_{22}$ are upper triangular and $R_{21}$ is strictly upper triangular. $R$ is called $J$-upper triangular. We get $A=S R$ with $S=T_{1}^{J} T_{2}^{J} \ldots T_{2 p-1} T_{2 p}^{J}$.

The algorithm SRSH involves free parameters. At each iteration $j$ of SRSH, two of the three parameters $r_{j j}, r_{j, p+j}, r_{j+p, j+p}$ can be chosen freely.
3. SR factorization via optimal symplectic Householder transformations. The SROSH algorithm corresponds to an efficient way of choosing the free parameters in the SRSH algorithm. It is based on the following result; see [13].

THEOREM 3.1. Let $[a, b] \in \mathbb{R}^{2 n \times 2}$, and let

$$
\rho=\operatorname{sign}\left(a_{1}\right)\|a\|_{2}, c_{1}=-\frac{1}{\rho a^{J} e_{1}}, v_{1}=a-\rho e_{1}, T_{1}=I+c_{1} v_{1} v_{1}^{J}
$$

Then $T_{1}$ has minimal 2-norm condition number and satisfies

$$
\begin{equation*}
T_{1}(a)=\rho e_{1} \tag{3.1}
\end{equation*}
$$

Let $u$ be the vector $u=T_{1}(b)$ and $u_{j}$ its $j$ th component, and let

$$
\begin{gathered}
\nu=u_{n+1}, \quad \xi=\left\|u-u_{1} e_{1}-u_{n+1} e_{n+1}\right\|_{2}, \quad \mu=u_{1} \pm \xi \\
c_{2}=-\frac{1}{ \pm \xi u_{n+1}}, \quad v_{2}=u-\mu e_{1}-u_{n+1} e_{n+1}, \quad T_{2}=I+c_{2} v_{2} v_{2}^{J}
\end{gathered}
$$

Then $T_{2}$ has minimal 2-norm condition number and satisfies

$$
\begin{equation*}
T_{2}\left(e_{1}\right)=e_{1} \text { and } T_{2}(u)=\mu e_{1}+\nu e_{n+1} \tag{3.2}
\end{equation*}
$$

We refer to $T_{1}, T_{2}$ as optimal symplectic Householder transformations.
REMARK 3.2. The vector $v_{2}$ differs from $u$ only by the first and $(n+1)$ th components and satisfies $v_{2}(n+1)=0$. This will be taken in consideration when storing $v_{2}$.
3.1. The SROSH algorithm. Given an input vector $a$, the procedure osh 1 below returns the coefficient $c_{1}$ and the vector $v_{1}$ for the optimal symplectic Householder transformation $T_{1}$ of Theorem 3.1. Similarly, the procedure osh2 computes the optimal symplectic Householder transformation $T_{2}$.

We normalize the optimal symplectic Householder vector of the procedure osh1 so that $v_{1}(1)=1$. Thus $v_{1}(2: 2 n)$ can be stored where the zeros have been introduced in $a$, i.e., $a(2: 2 n)$. As in the classical case, we refer to $v_{1}(2: 2 n)$ as the essential part of the optimal symplectic Householder vector of $T_{1}$. This gives the following procedure:

Algorithm 3.3. (First optimal symplectic Householder transformation) Given $a \in \mathbb{R}^{2 n}$, this function computes $v \in \mathbb{R}^{2 n}$ with $v(1)=1$ and $c \in \mathbb{R}$ such that $T=I+c v v^{J}$ is the optimal symplectic Householder transformation satisfying $T a=\rho e_{1}$ of Theorem 3.1.

```
function \([c, v]=\operatorname{osh} 1(a)\)
    den \(=\operatorname{length}(a) ; \quad n=\operatorname{den} / 2 ;\)
    \(J=[z \operatorname{zeros}(n), \operatorname{eye}(n) ;-\operatorname{eye}(n), \operatorname{zeros}(n)] ;\)
    \(\rho=\operatorname{sign}\left(a_{1}\right)\|a\|_{2} ; \quad\) aux \(=a(1)-\rho ;\)
    if \(a u x=0\)
        \(c=0 ; \quad v=0 ; \quad \% T=I ;\)
    else if \(a_{n+1}=0\)
        display('division by zero');
        return
    else
        \(v=\frac{a}{a u x} ; c=\frac{a u x^{2}}{\rho a_{n+1}} ; \quad v(1)=1 ;\)
        \(\% T=\left(e y e(d e n)+c * v * v^{\prime} * J\right) ;\)
    end
```

In a similar way, it is possible to normalize the optimal symplectic Householder vector $v_{2}$ so that $v_{2}(1)=1$. Moreover, since the $v_{2}(n+1)$ is zero. $v_{2}(2: 2 n)$ can be stored where the zeros have been introduced in $u$. This is clarified by the following figure. Such storage is not possible if the symplectic Householder transformation used is not optimal (since in this case, $v_{2}(n+1)$ is not necessarily zero).

$$
\left.\begin{array}{c} 
\\
{\left[\begin{array}{c}
u \\
u_{1} \\
u_{2} \\
\vdots \\
u_{n} \\
\hline u_{n+1} \\
u_{n+2} \\
\vdots \\
u_{2 n}
\end{array}\right]}
\end{array} \begin{array}{c}
T_{2} u \\
\times \\
T_{2} \\
0 \\
\vdots \\
0 \\
\hline \times \\
0 \\
\vdots \\
0
\end{array}\right] \quad \longleftarrow \quad\left[\begin{array}{c}
v_{2} \\
1 \\
v_{2}(2) \\
\vdots \\
v_{2}(n) \\
\hline 0 \\
v_{2}(n+2) \\
\vdots \\
v_{2}(2 n)
\end{array}\right]
$$

We refer to $v_{2}(2: 2 n)$ as the essential part of the optimal symplectic Householder vector of $T_{2}$.

Algorithm 3.4. (Second optimal symplectic Householder transformation)
Given $u \in \mathbb{R}^{2 n}$, this function computes $v \in \mathbb{R}^{2 n}$ with $v(1)=1$ and $c \in \mathbb{R}$ such that $T=I+c v v^{J}$ is the optimal symplectic Householder transformation satisfying $T e_{1}=e_{1}$ and $T u=\mu e_{1}+\nu e_{n+1}$ of Theorem 3.1.

```
function \([c, v]=\operatorname{osh} 2(u)\)
    den \(=\) length \((u) ; \quad n=\operatorname{den} / 2 ;\)
    \(J=[\operatorname{zeros}(n), \operatorname{eye}(n) ;-\operatorname{eye}(n), \operatorname{zeros}(n)] ;\)
    if \(n=1\)
        \(v=z e r o s(\operatorname{den}, 1) ; \quad c=0 ; \quad \% T=I\)
    else
        \(I=[2: n, n+2: d e n] ; \quad \xi=\operatorname{norm}(u(I)) ;\)
        if \(\xi=0\)
            \(v=\operatorname{zeros}(\operatorname{den}, 1) ; \quad c=0 ; \quad \% T=I ;\)
        else
            \(\nu=u(n+1) ; \quad \% \mu=u_{1}+\xi ;\) no need to compute \(\mu ;\)
            if \(u(n+1)=0\)
                display('division by zero')
                return
            else
                    \(v=-\frac{u}{\xi} ; \quad v(1)=1 ; \quad v(n+1)=0 ; \quad c=\frac{\xi}{u(n+1)} ;\)
            end
        end
    end
```

REMARK 3.5. The quantity $\xi$ also can be taken to be $-\operatorname{norm}(u(I))$ in Algorithm 3.4.
Note that the product of a symplectic Householder matrix $T=I+c v v^{J}$ with a given vector $a$ of dimension $2 n$ can be computed easily without explicitly forming $T$ itself, since

$$
T a=a+c v\left(v^{J} a\right)
$$

This formulation requires $8 n$ flops. If $A \in \mathbb{R}^{2 n \times 2 p}$ is a matrix, then the $T A$ can be written as $T A=A+c v\left(v^{J} A\right)=A+c v\left(v^{T} J A\right)=A+c v w^{T}$, where $w=-A^{T} J v$. Likewise, if $T=I+c v v^{T} J \in \mathbb{R}^{2 p \times 2 p}$, then

$$
A T=A\left(I+c v v^{T} J\right)=A+c w v^{T} J,
$$

where $w=c A v$. Hence, a $2 n$-by- $2 p$ symplectic Householder transformation is a rank-one matrix update and involves a matrix-vector multiplication and an outer product update. It requires 16 np flops. If $T$ is treated as a general matrix and the structure is not exploited, the amount of work increases by an order of magnitude. Thus, as in the classical case, symplectic Householder updates never entail the explicit formation of the symplectic Householder matrix. Note that both of the above Householder updates can be implemented in a way that exploits the fact that $v_{1}(1)=1$ for $T_{1}$ and $v_{2}(1)=1, v_{2}(n+1)=0$ for $T_{2}$.
3.2. Factored form representation. Many symplectic Householder-based factorization algorithms compute products of symplectic Householder matrices

$$
\begin{equation*}
S=T_{1} T_{n+1} T_{2} T_{n+2} \ldots T_{k} T_{n+k}, \quad T_{j}=I+c_{j} v^{(j)} v^{(j)^{T}} J \tag{3.3}
\end{equation*}
$$

where $k \leq n$ and the vectors $v^{(j)}, v^{(n+j)}, j=1, \ldots, k$ have the form

$$
\begin{aligned}
v^{(j)} & =\left[\begin{array}{llllllllll}
0_{j-1}^{T} & 1 & v_{j+1}^{(j)} & \ldots & v_{n}^{(j)} & \mid & 0_{j-1}^{T} & v_{n+j}^{(j)} & \ldots & v_{2 n}^{(j)}
\end{array}\right]^{T}, \\
v^{(n+j)} & =\left[\begin{array}{lllllllll}
0_{j-1}^{T} & 1 & v_{j+1}^{(n+j)} & \ldots & v_{n}^{(n+j)} & 0_{j}^{T} & v_{n+j+1}^{(n+j)} & \ldots & v_{2 n}^{(n+j)}
\end{array}\right]^{T} .
\end{aligned}
$$

It is not necessary to compute $S$ explicitly, even if $S$ is required in subsequent calculations. Thus, if a product $S^{J} B$ is needed, where $B \in \mathbb{R}^{2 n \times 2 k}$, then the following loop can be executed:

Algorithm 3.6.
for $j=1: k$

$$
\begin{aligned}
& B=T_{j} B \\
& B=T_{n+j} B
\end{aligned}
$$

end.
The storage of the symplectic Householder vectors $v^{(1)}, \ldots, v^{(k)}, v^{(n+1)}, \ldots, v^{(n+k)}$ and the corresponding $c_{j}$ amounts to a factored representation of $S$. For $b \in \mathbb{R}^{2 n}$, we examine carefully the implementation of the product $T_{j}^{J} b$. Set $H_{j}=c_{j} v^{(j)} v^{(j)^{T}}$; then $T_{j}^{J}=I-$ $H_{j} J_{2 n}$. Due to the structure of $v_{j}$, the submatrix $H_{j}([1: j-1, n+1: n+j-1],:)$, obtained from $H_{j}$ by deleting all rows except rows $1, \ldots, j-1$ and $n+1, \ldots, n+j-1$, is null. This implies that components $1, \ldots, j-1$ and $n+1, \ldots, n+j-1$ of $H_{j} J_{2 n} b$ vanish. Hence, the corresponding components of $T_{j}^{J} b$ remain unchanged. Similarly, the submatrix $H_{j}(:,[1: j-1, n+j: 2 n])$ (obtained from $H_{j}$ by deleting all columns except columns $1, \ldots, j-1$ and $n+j, \ldots, 2 n)$ is null. Setting rows $=[j: n, n+j: 2 n]$, one gets $\left[H_{j} J_{2 n} b\right]($ rows $)=\left[H_{j}\right]($ rows, rows $)\left[J_{2 n} b\right]($ rows $)$. It follows from the particular structure of $J_{2 n}$ that $\left[J_{2 n} b\right]$ (rows $)=J_{2(n-j+1)} b($ rows $)$. Thus, the product $T_{j}^{J} b$ is reduced to compute $b($ rows $)-\left[H_{j}\right]$ (rows, rows) $J_{2(n-j+1)} b($ rows $)$.

Suppose now that the essential part $v^{(j)}([j+1: n, n+j: 2 n])$ of the vector $v^{(j)}$ is stored in $A([j+1: n, n+j: 2 n], j)$, and similarly that $v^{(j+n)}([j+1: n, n+j+2: 2 n])$ is stored in $A([j+1: n, n+j+2: 2 n], n+j)$. The overwriting of $B$ with $S^{J} B$ can then be implemented as follows.

ALGORITHM 3.7. Product in factored form
for $j=1: k$;

$$
\begin{aligned}
& \text { rows }=[j: n, j+n: 2 n] ; \quad v(\text { rows })=\left[\begin{array}{c}
1 \\
A(j+1: n, j) \\
A(n+j: 2 n, j)
\end{array}\right] ; \\
& B(\text { rows },:)=B(\text { rows },:)-c_{j} v(\text { rows }) v(\text { rows })^{T} J_{2(n-j+1)} B(\text { rows },:) ; \\
& v(\text { rows })=\left[\begin{array}{c}
A(j+1: n, j+n) \\
0 \\
A(n+j+1: 2 n, j+n)
\end{array}\right] ; \\
& B(\text { rows },:)=B(\text { rows },:)-c_{j} v(\text { rows }) v(\text { rows })^{T} J_{2(n-j+1)} B(\text { rows },:) ;
\end{aligned}
$$

end
Algorithm 3.7 illustrates the economies of the factored form representation. It requires only $16 m k(2 n-k)$ flops. If $S$ is explicitly represented as a $2 n$-by- $2 n$ matrix, $S^{J} B$ would involves $16 n^{2} m$ flops.

REMARK 3.8. Note that in lines 3 and 5 of Algorithm 3.7, it should be $J_{2 n}$ (rows, rows) instead of $J_{2(n-j+1)}$. Due to the particular structure of $J$, we have $J_{2 n}($ rows, rows $)=$ $J_{2(n-j+1)}$. The interest of this fact is that the product $J_{2(n-j+1)} B($ rows, :) does not induce additional flops cost (the situation would be different if instead of $J$, one has a general matrix).

When it is necessary to compute $S$ explicitly, one can use a forward accumulation algorithm:

Algorithm 3.9.
$S=I_{2 n} ;$
for $j=1: k$

$$
\begin{aligned}
& \quad \begin{array}{l}
S=S T_{j} \\
S
\end{array} \\
& \text { end }
\end{aligned}
$$

Another option is to use a backward accumulation algorithm:
Algorithm 3.10.

$$
\begin{aligned}
& S=I_{2 n} \\
& \text { for } j=k:-1: 1 \\
& \qquad \begin{array}{l}
S=T_{j} S \\
\quad S=T_{n+j} S
\end{array} \\
& \text { end }
\end{aligned}
$$

Furthermore, it is important to note that backward accumulation requires fewer flops than forward accumulation. This is due to the particular structure of $T_{j}$. In fact, the block $(j-1)$ -by- $2 n$ (resp. $(n+j)$-by- $2 n$ ) of $T_{j}$ (resp. of $T_{n+j}$ ) is equal to the block $(j-1)$-by- $2 n$ (resp. $(n+j)$-by- $2 n$ ) of the identity. Hence, $S$ is "mostly the identity" at the beginning of backward accumulation and becomes gradually full as the iteration progresses. In contrast, $S$ is full in forward accumulation immediately after the first iteration. For this reason, backward accumulation is cheaper. It can be implemented with $32\left(n^{2} k-n k^{2}+k^{3} / 3\right)$ flops as follows.

Algorithm 3.11. Backward accumulation

$$
S=I_{2 n}
$$

for $j=k:-1: 1$

$$
\text { rows }=[j: n \quad j+n: 2 n] ;
$$

$$
v(\text { rows })=\left[\begin{array}{c}
1 \\
A(j+1: n, j+n) \\
0 \\
A(n+j+1: 2 n, j+n)
\end{array}\right]
$$

$$
S(\text { rows }, \text { rows })=S(\text { rows }, \text { rows })-c_{j} v(\text { rows }) v(\text { rows })^{T} J_{2(n-j+1)} S(\text { rows }, \text { rows })
$$

$$
v(\text { rows })=\left[\begin{array}{c}
1 \\
A(j+1: n, j) \\
A(n+j: 2 n, j)
\end{array}\right]
$$

end

$$
S(\text { rows }, \text { rows })=S(\text { rows }, \text { rows })-c_{j} v(\text { rows }) v(\text { rows })^{T} J_{2(n-j+1)} S(\text { rows , rows })
$$

3.3. A block representation. Suppose that $S=T_{1} T_{n+1} T_{2} T_{n+2} \ldots T_{k} T_{n+k}$ is a product of $2 n$-by $-2 n$ optimal symplectic Householder matrices as in (3.3). Since each $T_{j}$ is a rank-one modification of the identity, it follows from the structure of the symplectic Householder vectors that $S$ is a rank- $2 k$ modification of the identity and can be written in the form

$$
\begin{equation*}
S=I+W Y^{T} J \tag{3.4}
\end{equation*}
$$

where $W$ and $Y$ are $2 n$-by- $2 k$ matrices. We refer to this block representation as a $J-W Y$ representation. Its computation is based on the following lemma.

Lemma 3.12. Suppose that $S=I+W Y^{T} J$ is an $2 n$-by- $2 n$ symplectic matrix with $W, Y \in \mathbb{R}^{2 n \times j}$. If $T=I+c v v^{T} J$ with $v \in \mathbb{R}^{2 n}$ and $z=c S v$, then

$$
S T=I+W_{+} Y_{+}^{T} J
$$

where $W_{+}=\left[\begin{array}{ll}W & z\end{array}\right]$ and $Y_{+}=\left[\begin{array}{ll}Y & v\end{array}\right]$ are $2 n$-by- $(j+1)$ matrices.
Proof.

$$
\begin{aligned}
S T & =\left(I+W Y^{T} J\right)\left(I+c v v^{T} J\right)=I+W Y^{T} J+c S v v^{T} J \\
& =I+W Y^{T} J+z v^{T} J=I+\left[\begin{array} { l l } 
{ W } & { z }
\end{array} \left[\begin{array}{ll}
Y & ]^{T} J
\end{array}\right.\right.
\end{aligned}
$$

The block representation of $S$ can be generated from the factored form by repeatedly applying the Lemma 3.12 as follows.

## Algorithm 3.13. Block representation

Suppose that $S=T_{1} T_{n+1} T_{2} T_{n+2} \ldots T_{k} T_{n+k}$ is a product of $2 n-$ by $-2 n$ optimal symplectic Householder matrices as in (3.3). This algorithm computes matrices $W, Y \in \mathbb{R}^{2 n \times 2 k}$ such that $S=I+W Y^{T} J$.

$$
\begin{aligned}
& Y=v^{(1)} ; W=c_{1} v^{(1)} ; \\
& z=c_{n+1}\left(I+W Y^{T} J\right) v^{(n+1)} ; \\
& W=[W z] ; Y=\left[Y v^{[n+1]}\right] \\
& \text { for } j=2: k \\
& \quad z=c_{j}\left(I+W Y^{T} J\right) v^{(j)} ; \\
& \quad W=[W z] ; Y=\left[Y v^{(j)}\right] ; \\
& \quad z=c_{n+j}\left(I+W Y^{T} J\right) v^{(n+j)} \\
& \quad W=[W z] ; \quad Y=\left[Y v^{(n+j)}\right]
\end{aligned}
$$

end.
This algorithm requires about $16\left(k^{2} n-k^{3} / 3\right)$ flops if the zeros in $v^{(j)}$ and $v^{(n+j)}$ are exploited. Note that $Y$ is obviously the matrix of symplectic Householder vectors up a permutation of columns. Clearly, the central task in the generation of the $J-W Y$ representation (3.4) is the computation of the $W$ matrix.

The block representation of products of symplectic Householder matrices is attractive in situations where $S$ must be applied to a matrix. Suppose that $C \in \mathbb{R}^{2 n \times 2 k}$. It follows that the operation $C \longleftarrow S^{J} C=\left(I+W Y^{T} J\right)^{J} C=C-Y\left(W^{T} J C\right)$ is rich in level-3 operations. If $S$ is in factored form, $S^{J} C$ is just rich in the level-2 operations of matrix-vector multiplication and outer products updates.

We mention that the $J-W Y$ representation is not a generalized symplectic Householder transformation from the geometric point of view. True symplectic block reflectors are discussed in [11].
3.4. The SROSH algorithm. The steps of the SROSH algorithm are the same as those of the SRSH algorithm. The only change is that the free parameters in SRSH are replaced by optimal ones in SROSH. Let $A \in \mathbb{R}^{2 n \times 2 p}$ and assume that $p \leq n$. Given $j \leq m \leq k \leq 2 n$ and $j^{\prime} \leq m^{\prime} \leq k^{\prime} \leq 2 p$, let $A\left([j: m, k: 2 n],\left[j^{\prime}: m^{\prime}, k^{\prime}: 2 p\right]\right)$ denote the submatrix obtained from $A$ by deleting all rows except rows $j, \ldots, m$ and $k, \ldots, 2 n$ and all columns except columns $j^{\prime}, \ldots, m^{\prime}$ and $k^{\prime}, \ldots, 2 p$.

ALGORITHM 3.14. SROSH algorithm, factored form
Given $A \in \mathbb{R}^{2 n \times 2 p}$ with $n \geq p$, the following algorithm finds (implicitly) optimal symplectic Householder matrices $T_{1}, \ldots, T_{2 p}$ such that if $S^{J}=T_{2 p}^{J} T_{p}^{J} \ldots T_{p+1}^{J} T_{1}^{J}$, then $S^{J} A=R$ is $J$-upper triangular. The $J$-upper triangular part of $A$ is overwritten by the $J$-upper triangular part of $R$, and the essential part of the optimal symplectic Householder vectors are stored in the zeroed portion of $A$.

$$
\begin{aligned}
& \text { for } j=1: p \\
& \quad r o=[j: n, n+j: 2 n] ; c o=[j: p, p+j: 2 p] ; \\
& \quad\left[c, v_{1}\right]=\operatorname{osh} 1(A(r o,[j])) ; \\
& A(r o, c o)=A(r o, c o)+c v_{1} v_{1}^{T} J A(r o, c o) ; \\
& {\left[c, v_{2}\right]=o s h 2(A(r o,[p+j])) ;} \\
& A(r o, c o)=A(r o, c o)+c v_{2} v_{2}^{T} J A(r o, c o) ; \\
& \quad \text { if } j<n
\end{aligned}
$$

```
        \(A(j+1: n, j)=v_{1}(2: n-j+1)\);
        \(A(j+n: 2 n, j)=v_{1}(n-j+2: 2(n-j+1))\);
        \(A(j+1: n, j+p)=v_{2}(2: n-j+1)\);
        \(A(j+1+n: 2 n, j+p)=v_{2}(n-j+3: 2(n-j+1)) ;\)
    else
        \(A(j+n: 2 n, p)=v_{1}(2) ;\)
        end
end
```

This algorithm requires $16 m^{2}(n-p / 3)$ flops. To clarify how $A$ is overwritten, we give the following example:

$$
A=\left[\begin{array}{cccccc}
r_{11} & r_{12} & r_{13} & r_{14} & r_{15} & r_{16} \\
v_{1}(2) & r_{22} & r_{23} & v_{4}(2) & r_{25} & r_{26} \\
v_{1}(3) & v_{2}(3) & r_{33} & v_{4}(3) & v_{5}(3) & r_{36} \\
v_{1}(4) & r_{42} & r_{43} & r_{44} & r_{45} & r_{46} \\
v_{1}(5) & v_{2}(5) & r_{53} & v_{4}(5) & r_{55} & r_{36} \\
v_{1}(6) & v_{2}(6) & v_{3}(6) & v_{4}(6) & v_{5}(6) & r_{36}
\end{array}\right]
$$

If the matrix $S$ is required, it can be computed in $32\left(n^{2} p-n p^{2}+p^{3} / 3\right)$ flops using backward accumulation. Note that due to (2.7), computing the product $S^{J}=T_{2 p}^{J} T_{p}^{J} \ldots T_{p+1}^{J} T_{1}^{J}$ does not cost any more flops due of the presence of $J$-transpositions.

## 4. Error analysis of SROSH.

4.1. Background for error analysis. To carry out a rounding error analysis of the SROSH algorithm, we adopt the standard model for floating operations

$$
\begin{equation*}
f l(x \text { op } y)=(x \text { op } y)(1+\delta), \quad|\delta| \leq \mathbf{u}, \quad \text { op }=+,-, *, / \tag{4.1}
\end{equation*}
$$

The quantity $\mathbf{u}$ stands for the unit roundoff. In the following analysis and throughout the paper, a hat denotes a computed quantity. We now recall some important notations, conventions, and results of rounding error analysis developed in [7]. We will use these results in what follows to derive a rounding error analysis for the SROSH algorithm.

LEMMA 4.1. If $\left|\delta_{i}\right| \leq \mathbf{u}$, and $\rho_{i}= \pm 1$ for $i=1: n$ and $n \mathbf{u}<1$, then

$$
\prod_{i=1}^{n}\left(1+\delta_{i}\right)^{\rho_{i}}=1+\theta_{n}
$$

where

$$
\left|\theta_{n}\right| \leq \frac{n \mathbf{u}}{1-n \mathbf{u}}=: \gamma_{n}
$$

Proof. See [7, pp. 63]. $\square$
The $\theta_{n}$ and $\gamma_{n}$ notation is used throughout this section. It is implicitly assumed that $n \mathbf{u}<1$ (which is usually satisfied), whenever we write $\gamma_{n}$. Consider the inner product $s_{n}=x^{T} y$, where $x, y \in \mathbb{R}^{n}$. Using Lemma 4.1, the computed $\hat{s}_{n}$ is then given by

$$
\begin{equation*}
\hat{s}_{n}=x_{1} y_{1}\left(1+\theta_{n}\right)+x_{2} y_{2}\left(1+\theta_{n}^{\prime}\right)+x_{3} y_{3}\left(1+\theta_{n-1}\right)+\ldots+x_{n} y_{n}\left(1+\theta_{2}\right) \tag{4.2}
\end{equation*}
$$

with $\left|\theta_{i}\right| \leq \gamma_{i} \leq \gamma_{n}, i=1: n, \theta_{n}^{\prime} \leq \gamma_{n}$, and thus each relative perturbation is certainly bounded by $\gamma_{n}$. Hence, we obtain

$$
\begin{equation*}
f l\left(x^{T} y\right)=\hat{s}_{n}=(x+\Delta x)^{T} y=x^{T}(y+\Delta y), \quad|\Delta x| \leq \gamma_{n}|x|, \quad|\Delta y| \leq \gamma_{n}|y| \tag{4.3}
\end{equation*}
$$

where $|x|$ denotes the vector such that $|x|_{i}=\left|x_{i}\right|$ and inequalities between vectors (or matrices) hold componentwise. The result (4.3) means that computation of an inner product is a backward stable process.

For an outer product $A=x y^{T}$, we have $\hat{a}_{i j}=x_{i} y_{j}\left(1+\delta_{i j}\right),\left|\delta_{i j}\right| \leq \mathbf{u}$, so

$$
\begin{equation*}
\hat{A}=x y^{T}+\Delta, \quad|\Delta| \leq \mathbf{u}\left|x y^{T}\right| \tag{4.4}
\end{equation*}
$$

The computation of an outer product is not backward stable. Nevertheless, (4.4) is a satisfactory result.

The following lemma provides some necessary rules for manipulating the $1+\theta_{k}$ and $\gamma_{k}$ terms involved in Lemma 4.1.

LEMMA 4.2. For any positive integer $k$, let $\theta_{k}$ denote a quantity bounded according to

$$
\left|\theta_{k}\right| \leq \gamma_{k}=\frac{k \mathbf{u}}{1-k \mathbf{u}}
$$

The following relations hold:

$$
\begin{gathered}
\left(1+\theta_{k}\right)\left(1+\theta_{j}\right)=\left(1+\theta_{k+j}\right), \quad \frac{1+\theta_{k}}{1+\theta_{j}}= \begin{cases}1+\theta_{k+j}, & j \leq k \\
1+\theta_{k+2 j}, & j>k\end{cases} \\
\quad \gamma_{k} \gamma_{j} \leq \gamma_{\min (k, j)} \text { for } \max (j, k) \mathbf{u} \leq 1 / 2, \\
i \gamma_{k} \leq \gamma_{i k}, \quad \gamma_{k}+\mathbf{u} \leq \gamma_{k+1}, \quad \gamma_{k}+\gamma_{j}+\gamma_{k} \gamma_{j} \leq \gamma_{k+j}
\end{gathered}
$$

Proof. See [7, pp. 67].
It is straightforward to analyze matrix-vector and matrix-matrix products, once error analysis for inner products has been given. Let $A \in \mathbb{R}^{m \times n}, x \in \mathbb{R}^{n}$, and $y=A x$. We have the backward error result

$$
\begin{equation*}
\hat{y}=(A+\Delta A) x, \quad|\Delta A| \leq \gamma_{n}|A| \tag{4.5}
\end{equation*}
$$

The following result is needed.
Lemma 4.3. If $X_{j}+\Delta X_{j} \in \mathbb{R}^{m \times m}$ satisfies $\left\|\Delta X_{j}\right\|_{F} \leq \delta_{j}\left\|X_{j}\right\|_{2}$ for all $j$, then

$$
\left\|\prod_{j=0}^{p}\left(X_{j}+\Delta X_{j}\right)-\prod_{j=0}^{p} X_{j}\right\|_{F} \leq\left(\prod_{j=0}^{p}\left(1+\delta_{j}\right)-1\right) \prod_{j=0}^{p}\left\|X_{j}\right\|_{2}
$$

Proof. See [7, pp. 73].
4.2. Error analysis for optimal symplectic Householder transformations. In the following analysis, it is not worthwhile to keep the precise value of the integer constants in the $\gamma_{k}$ terms. We make use of the notation $\tilde{\gamma}_{k}=c k \mathbf{u} /(1-c k \mathbf{u})$, where $c$ denotes a small integer constant; see [7]. For example, we write $4 \gamma_{n} \leq \gamma_{4 n}=\tilde{\gamma}_{n}$.

Lemma 4.4. Consider the optimal symplectic Householder transformation $T_{1}=I+$ $c_{1} v_{1} v_{1}^{J}$ given by Algorithm 3.3. The computed $\hat{c}_{1}$ and $\hat{v}_{1}$ satisfy $\hat{v}_{1}(2: 2 n)=v_{1}(2: 2 n)$ and

$$
\begin{equation*}
\hat{c}_{1}=c_{1}\left(1+\tilde{\theta}_{2 n}\right), \quad \hat{v}_{1}(1)=v_{1}(1)\left(1+\tilde{\theta}_{2 n}\right) \tag{4.6}
\end{equation*}
$$

where $\left|\tilde{\theta}_{2 n}\right| \leq \tilde{\gamma}_{2 n}$.

Proof. We mention that each occurrence of $\delta$ denotes a different number bounded by $\delta \leq \mathbf{u}$. We have $\rho=\operatorname{sign}\left(a_{1}\right)\|a\|_{2}$ and $v_{1}(1)=a_{1}-\rho$, and we use the formula

$$
v_{1}(1)=\frac{a_{1}^{2}-\rho^{2}}{a_{1}+\rho}=-\frac{a_{2}^{2}+\ldots+a_{2 n}^{2}}{a_{1}+\rho}
$$

to avoid cancellation errors in computing $v_{1}(1)$. Setting $d=a_{2}^{2}+\ldots+a_{2 n}^{2}$ and $e=d+a_{1}^{2}$, we get $\hat{d}=d\left(1+\theta_{2 n-1}\right)$, and then $\hat{e}=\left(\hat{d}+a_{1}^{2}(1+\delta)\right)(1+\delta)=\left(d+a_{1}^{2}\right)\left(1+\theta_{2 n}\right)$ (because there is cancellation in the sum). Setting $f=\sqrt{\hat{e}}$, we obtain

$$
\hat{f}=\sqrt{\hat{e}}(1+\delta)=\left(d+a_{1}^{2}\right)^{1 / 2}\left(1+\theta_{2 n}\right)^{1 / 2}(1+\delta)=\left(d+a_{1}^{2}\right)^{1 / 2}\left(1+\theta_{2 n+1}\right)
$$

Since $\rho=\operatorname{sign}\left(a_{1}\right)\left(d+a_{1}^{2}\right)^{1 / 2}$, it follows that

$$
\hat{\rho}=\operatorname{sign}\left(a_{1}\right) \hat{f}=\operatorname{sign}\left(a_{1}\right)\left(d+a_{1}^{2}\right)^{1 / 2}\left(1+\theta_{2 n+1}\right)
$$

and thus

$$
\begin{equation*}
\hat{\rho}=\rho\left(1+\theta_{2 n+1}\right) . \tag{4.7}
\end{equation*}
$$

From $v_{1}(1)=-d /\left(a_{1}+\rho\right)$, we deduce

$$
\hat{v}_{1}(1)=-\frac{\hat{d}(1+\delta)}{\left(a_{1}+\hat{\rho}\right)(1+\delta)}
$$

Since there is no cancellation in the sum $a_{1}+\hat{\rho}$ and using (4.7), we obtain

$$
\hat{v}_{1}(1)=-\frac{\hat{d}(1+\delta)}{\left(a_{1}+\rho\right)\left(1+\theta_{2 n+2}\right)}=-\frac{d\left(1+\theta_{2 n}\right)}{\left(a_{1}+\rho\right)\left(1+\theta_{2 n+2}\right)}
$$

Furthermore, by applying Lemma 4.1, we get

$$
\hat{v}_{1}(1)=-\frac{d}{a_{1}+\rho}\left(1+\theta_{6 n+4}\right)=v_{1}(1)\left(1+\theta_{6 n+4}\right) .
$$

From

$$
\left|\tilde{\theta}_{2 n}\right|=\left|\theta_{6 n+4}\right| \leq \gamma_{6 n+4} \leq \gamma_{8 n}=\tilde{\gamma}_{2 n}
$$

we obtain

$$
\hat{v}_{1}(1)=v_{1}(1)\left(1+\tilde{\theta}_{2 n}\right) \text { and }\left|\Delta v_{1}(1)\right| \leq\left|v_{1}(1)\right| \tilde{\gamma}_{2 n}
$$

Lemma 4.5. Consider the optimal symplectic Householder transformation $T_{2}=I+$ $c_{2} v_{2} v_{2}^{J}$ given by Algorithm 3.4. The computed $\hat{c}_{2}$ and $\hat{v}_{2}$ satisfy $\hat{v}_{2}(2: 2 n)=v_{2}(2: 2 n)$, and

$$
\begin{equation*}
\hat{c}_{2}=c_{2}\left(1+\tilde{\theta}_{2 n}\right), \quad \hat{v}_{2}(1)=v_{2}(1)\left(1+\tilde{\theta}_{2 n}\right) \tag{4.8}
\end{equation*}
$$

where $\left|\tilde{\theta}_{2 n}\right| \leq \tilde{\gamma}_{2 n}$.
Proof. We have $v_{2}(1)=-\xi=-\left(a_{2}^{2}+\ldots+a_{n}^{2}+a_{n+2}^{2}+\ldots+a_{2 n}\right)^{1 / 2}$. Thus, we get $\hat{\xi}=\xi\left(1+\theta_{2 n-1}\right)$ and hence $\hat{v}_{2}(1)=-\hat{\xi}=v_{2}(1)\left(1+\tilde{\theta}_{2 n}\right)$. Similar to the results of the analysis of $c_{2}=1 /\left(\xi u_{n+1}\right)$, we find

$$
\hat{c}_{2}=\frac{(1+\delta)^{2}}{\hat{\xi} u_{n+1}}=\frac{(1+\delta)^{2}}{\xi\left(1+\theta_{2 n-1}\right) u_{n+1}} .
$$

From Lemma 4.1, we then obtain

$$
\hat{c}_{2}=\frac{1}{\xi u_{n+1}}\left(1+\theta_{4 n}\right)=c_{2}\left(1+\tilde{\theta}_{2 n}\right)
$$

The next result describes the application of a symplectic Householder transformation to a vector, and is the basis of the subsequent analysis. For convenience we here write symplectic Householder matrices in the form $T_{1}=I+w_{1} v_{1}^{J}$ and $T_{2}=I+w_{2} v_{2}^{J}$, which requires $w_{1}=c_{1} v_{1}$ and $w_{2}=c_{2} v_{2}$. Using then Lemmas 4.4 and 4.5, we obtain

$$
\begin{align*}
& \hat{w}_{1}=w_{1}+\Delta w_{1}, \quad\left|\Delta w_{1}\right| \leq \tilde{\gamma}_{2 n}\left|w_{1}\right|, \text { and } \\
& \hat{w}_{2}=w_{2}+\Delta w_{2}, \quad\left|\Delta w_{2}\right| \leq \tilde{\gamma}_{2 n}\left|w_{2}\right| \tag{4.9}
\end{align*}
$$

LEMMA 4.6. Let $b \in \mathbb{R}^{2 n}$, and consider the computation of $y=\hat{T}_{1} b=\left(I+\hat{w}_{1} \hat{v}_{1}^{J}\right) b$ where $\hat{v}_{1}$ and $\hat{w}_{1}$ satisfy (4.6) and (4.9), respectively. The computed $\hat{y}$ satisfies

$$
\begin{equation*}
\hat{y}=\left(T_{1}+\Delta T_{1}\right) b, \quad\left\|\Delta T_{1}\right\|_{F} \leq 3 \tilde{\gamma}_{2 n}\left\|T_{1}\right\|_{2} \tag{4.10}
\end{equation*}
$$

## Moreover,

$$
\begin{equation*}
\left\|\Delta T_{1}\right\|_{F} \leq 5 \tilde{\gamma}_{2 n} \frac{\|a\|_{2}}{\left|a_{n+1}\right|} \tag{4.11}
\end{equation*}
$$

Proof. We have

$$
\hat{z}=f l\left(\hat{w}_{1}\left(\hat{v}_{1}^{J} b\right)\right)=\left(\hat{w}_{1}+\Delta \hat{w}_{1}\right)\left(\hat{v}_{1}^{J}(b+\Delta b)\right)
$$

where $\left|\Delta \hat{w}_{1}\right| \leq \mathbf{u}\left|\hat{w}_{1}\right|$ and $|\Delta b| \leq \gamma_{2 n}|b|$. Hence

$$
\hat{z}=\left(w_{1}+\Delta w_{1}+\Delta \hat{w}_{1}\right)\left(v_{1}+\Delta v_{1}\right)^{J}(b+\Delta b)=w_{1}\left(v_{1}^{J} b\right)+\Delta z
$$

where $|\Delta z| \leq \tilde{\gamma}_{2 n}\left|w_{1}\right|\left|v_{1}^{J}\right||b|$. It follows that

$$
\hat{y}=f l(b+\hat{z})=b+w_{1}\left(v_{1}^{J} b\right)+\Delta z+\Delta y_{1}, \quad\left|\Delta y_{1}\right| \leq \mathbf{u}|b+\hat{z}|
$$

We get

$$
\begin{equation*}
\left|\Delta z+\Delta y_{1}\right| \leq \mathbf{u}|b|+\tilde{\gamma}_{2 n}\left|w_{1}\right|\left|v_{1}^{J}\right||b| . \tag{4.12}
\end{equation*}
$$

Setting $\Delta y=\Delta z+\Delta y_{1}$ and $\Delta T_{1}=\left(\Delta y b^{T}\right) /\left(b^{T} b\right)$, we obtain

$$
\hat{y}=T_{1} b+\Delta y=\left(T_{1}+\Delta T_{1}\right) b, \quad\left\|\Delta T_{1}\right\|_{F}=\frac{\|\Delta y\|_{2}}{\|b\|_{2}} .
$$

From (4.12), we have

$$
\|\Delta y\|_{2} \leq \mathbf{u}\|b\|_{2}+\tilde{\gamma}_{2 n}\left\|\left|w_{1}\right|\left|v_{1}^{J}\right|\right\|_{2}\|b\|_{2} \leq \tilde{\gamma}_{2 n}\left(1+\left\|\left|w_{1}\right|\left|v_{1}^{J}\right|\right\|_{2}\right)\|b\|_{2}
$$

Since

$$
\left\|\left|w_{1}\right|\left|v_{1}^{J}\right|\right\|_{2}=\left\|\left|w_{1}\right|\right\|_{2}\| \| v_{1}^{J} \mid\left\|_{2}=\right\| w_{1}\left\|_{2}\right\| v_{1}^{J}\left\|_{2}=\right\| w_{1} v_{1}^{J}\left\|_{2}=\right\| I-T_{1}\left\|_{2} \leq 1+\right\| T_{1} \|_{2}
$$

we then get

$$
\left\|\Delta T_{1}\right\|_{F}=\frac{\|\Delta y\|_{2}}{\|b\|_{2}} \leq \tilde{\gamma}_{2 n}\left(2+\left\|T_{1}\right\|_{2}\right) \leq 3 \tilde{\gamma}_{2 n}\left\|T_{1}\right\|_{2}
$$

Substituting $w_{1}=c_{1} v_{1}$ in (4.12), $\|\Delta y\|_{2}$ can be bounded by

$$
\|\Delta y\|_{2} \leq \mathbf{u}\|b\|_{2}+\tilde{\gamma}_{2 n}\left|c_{1}\right|\left\|v_{1}\right\|_{2}^{2}\|b\|_{2}
$$

and thus

$$
\left\|\Delta T_{1}\right\|_{F}=\frac{\|\Delta y\|_{2}}{\|b\|_{2}} \leq \mathbf{u}+\tilde{\gamma}_{2 n}\left|c_{1}\right|\left\|v_{1}\right\|_{2}^{2}
$$

Since

$$
\left|c_{1}\right|=\frac{\left(\left|a_{1}\right|-\|a\|_{2}\right)^{2}}{\|a\|_{2} a_{n+1}} \text { and }\left\|v_{1}\right\|_{2}^{2}=1+\frac{\|a\|_{2}^{2}-a_{1}^{2}}{\left(\left|a_{1}\right|-\|a\|_{2}\right)^{2}}=2 \frac{\|a\|_{2}}{\|a\|_{2}-\left|a_{1}\right|}
$$

it follows that

$$
\left|c_{1}\right|\left\|v_{1}\right\|_{2}^{2}=\frac{2\left(\|a\|_{2}-\left|a_{1}\right|\right)}{\left|a_{n+1}\right|}
$$

Hence,

$$
\left\|\Delta T_{1}\right\|_{F} \leq \mathbf{u}+\tilde{\gamma}_{2 n} \frac{4\|a\|_{2}}{\left|a_{n+1}\right|} \leq 5 \tilde{\gamma}_{2 n} \frac{\|a\|_{2}}{\left|a_{n+1}\right|}
$$

REMARK 4.7. A very interesting exploitation of (4.11) is to use a strategy of pivoting in the process of optimal symplectic Householder SR factorization, with symplectic permutations so that the ratio $\|a\|_{2} /\left|a_{n+1}\right|$ is minimal.

Next, we consider a sequence of optimal symplectic Householder transformations applied to a matrix.

LEMMA 4.8. Let $\left(A_{k}\right)$ be the sequence of matrices given by

$$
A_{k+1}=T_{k} A_{k}, \quad k=1: r
$$

where $A_{1}=A \in \mathbb{R}^{2 n \times 2 m}$ and $T_{k}=I+w_{k} v_{k}^{J} \in \mathbb{R}^{2 n \times 2 n}$ is a (optimal) symplectic Householder matrix. Assume that

$$
\begin{equation*}
r \tilde{\gamma}_{2 n}<\frac{1}{2} \tag{4.13}
\end{equation*}
$$

Then the computed matrix $\hat{A}_{r+1}$ satisfies

$$
\begin{equation*}
\hat{A}_{r+1}=S(A+\Delta A) \tag{4.14}
\end{equation*}
$$

where $S=T_{r} T_{r-1} \ldots T_{1}$ and

$$
\begin{align*}
\|S \Delta A\|_{2} & \leq \frac{3 r \tilde{\gamma}_{2 n}}{1-3 r \tilde{\gamma}_{2 n}} \prod_{i=1}^{r}\left\|T_{i}\right\|_{2}\|A\|_{2}  \tag{4.15}\\
\|\Delta A\|_{2} & \leq \frac{3 r \tilde{\gamma}_{2 n}}{1-3 r \tilde{\gamma}_{2 n}} \prod_{i=1}^{r} \kappa_{2}\left(T_{i}\right)\|A\|_{2} \tag{4.16}
\end{align*}
$$

Proof. The matrix $A_{r+1}$ is given by $A_{r+1}=T_{r} T_{r-1} \ldots T_{1} A$. By Lemma 4.6, we have

$$
\begin{equation*}
\hat{A}_{r+1}=\left(T_{r}+\Delta T_{r}\right) \ldots\left(T_{1}+\Delta T_{1}\right) A \tag{4.17}
\end{equation*}
$$

where each $\Delta T_{k}$ satisfies $\left\|\Delta T_{k}\right\|_{F} \leq 3 \tilde{\gamma}_{2 n}\left\|T_{k}\right\|_{2}$. Using Lemma 4.3 and assumption (4.13), we obtain $\hat{A}_{r+1}=S(A+\Delta A)$, where

$$
\begin{equation*}
\|S \Delta A\|_{2} \leq\left(\left(1+3 \tilde{\gamma}_{2 n}\right)^{r}-1\right) \prod_{i=1}^{r}\left\|T_{i}\right\|_{2}\|A\|_{2} \leq \frac{3 r \tilde{\gamma}_{2 n}}{1-3 r \tilde{\gamma}_{2 n}} \prod_{i=1}^{r}\left\|T_{i}\right\|_{2}\|A\|_{2} \tag{4.18}
\end{equation*}
$$

Then $\|\Delta A\|_{2}$ can be bounded by

$$
\|\Delta A\|_{2}=\left\|S^{J} S \Delta A\right\|_{2} \leq\|S \Delta A\|_{2}\left\|S^{J}\right\|_{2} \leq\|S \Delta A\|_{2} \prod_{i=1}^{r}\left\|T_{i}^{-1}\right\|_{2}
$$

Using (4.18), we get

$$
\begin{aligned}
\|\Delta A\|_{2} & \leq \frac{3 r \tilde{\gamma}_{2 n}}{1-3 r \tilde{\gamma}_{2 n}}\left(\prod_{i=1}^{r}\left\|T_{i}\right\|_{2}\right)\left(\prod_{i=1}^{r}\left\|T_{i}^{-1}\right\|_{2}\right)\|A\|_{2} \\
& \leq \frac{3 r \tilde{\gamma}_{2 n}}{1-3 r \tilde{\gamma}_{2 n}} \prod_{i=1}^{r} \kappa_{2}\left(T_{i}\right)\|A\|_{2}
\end{aligned}
$$

Lemma 4.8 yields the standard backward and forward error results for symplectic Householder SR factorization.

THEOREM 4.9. Let $\hat{R} \in \mathbb{R}^{2 n \times 2 m}$ be the computed J-upper trapezoidal SR factor of $A \in \mathbb{R}^{2 n \times 2 m}(n \geq m)$ obtained via the $S R$ optimal symplectic Householder algorithm SROSH. Then there exists a symplectic $S \in \mathbb{R}^{2 n \times 2 n}$ such that

$$
A+\Delta A=S \hat{R}
$$

where

$$
\begin{equation*}
\|\Delta A\|_{2} \leq \frac{6 m \tilde{\gamma}_{2 n}}{1-6 m \tilde{\gamma}_{2 n}}\|A\|_{2} \prod_{i=1}^{2 m} \kappa_{2}\left(T_{i}\right) \tag{4.19}
\end{equation*}
$$

The matrix $S$ is given explicitly by $S=\left(\hat{T}_{2 m} \hat{T}_{2 m-1} \ldots \hat{T}_{1}\right)^{J}$, where $\hat{T}_{i}$ is the symplectic Householder matrix that corresponds to the exact application of the ith step of the algorithm to $\hat{A}_{k}$.

Proof. This is a direct application of Lemma 4.8, with $T_{k}$ (resp. $T_{k+m}$ ) defined as the optimal symplectic Householder transformation that produces zeros in the desired entries in the $k$ th (resp. the $(k+m)$ th) column of the computed matrix $\hat{A}_{k}$. Note that in this algorithm, we do not compute the null elements of $\hat{R}$ explicitly, but rather set them to zero explicitly. Nevertheless, the conclusions of Lemmas 4.6 and 4.8 are still valid. The reason is that the elements of $\Delta T_{1} b$ (respectively $\Delta T_{2} b$ ) in Lemma 4.6 that correspond to elements that are zeroed by the optimal symplectic Householder transformation $T_{1}$ (respectively $T_{2}$ ) are forced to be zero, and hence we can set the corresponding rows of $\Delta T_{1}$ (respectively $\Delta T_{2}$ ) to zero, too, without compromising the bound for $\left\|\Delta T_{1}\right\|_{F}$ (respectively $\left\|\Delta T_{2}\right\|_{F}$ ). $\square$

Note that the matrix $S$ in Theorem 4.9 is not computed by the optimal symplectic Householder SR factorization algorithm and is of purely theoretical interest. The fact that $S$ is exactly symplectic makes the result so useful. When $S$ is explicitly formed, two questions arise:

1. How close is the computed $\hat{S}$ to being symplectic?
2. How large is $A-\hat{S} \hat{R}$ ?

Using the analysis above, these questions are answered as follows.
THEOREM 4.10. Let $\hat{R} \in \mathbb{R}^{2 n \times 2 m}$ be the computed $J$-upper trapezoidal $S R$ factor of $A \in \mathbb{R}^{2 n \times 2 m}(n \geq m)$ obtained via the SR optimal symplectic Householder algorithm SROSH and $\hat{S}$ the computed factor of the product $S=\hat{T}_{1}{ }^{J} \hat{T}_{2}{ }^{J} \ldots \hat{T}_{2 m}^{J}$ evaluated in the more efficient right-to-left order. Then

$$
\begin{equation*}
\|\hat{S}-S\|_{2} \leq \frac{6 m \tilde{\gamma}_{2 n}}{1-6 m \tilde{\gamma}_{2 n}} \prod_{i=1}^{2 m}\left\|T_{i}\right\|_{2} \tag{4.20}
\end{equation*}
$$

Moreover,

$$
\begin{equation*}
\|(A-\hat{S} \hat{R})\|_{2} \leq \frac{6 m \tilde{\gamma}_{2 n}}{1-6 m \tilde{\gamma}_{2 n}}\left(1+\frac{1}{1-6 m \tilde{\gamma}_{2 n}}\right)\|A\|_{2} \prod_{i=1}^{2 m} \kappa_{2}\left(T_{i}\right) \tag{4.21}
\end{equation*}
$$

Proof. Lemma 4.8 gives (with $A_{1}=I_{2 n}$ )

$$
\hat{S}=S\left(I_{2 n}+\Delta I\right), \quad\|S-\hat{S}\|_{2}=\|S \Delta I\|_{2} \leq \frac{6 m \tilde{\gamma}_{2 n}}{1-6 m \tilde{\gamma}_{2 n}} \prod_{i=1}^{2 m}\left\|T_{i}\right\|_{2}
$$

Using Theorem 4.9, we have

$$
\begin{aligned}
\|(A-\hat{S} \hat{R})\|_{2} & =\|(A-S \hat{R})+((S-\hat{S}) \hat{R})\|_{2} \\
& \leq \frac{6 m \tilde{\gamma}_{2 n}}{1-6 m \tilde{\gamma}_{2 n}}\|A\|_{2} \prod_{i=1}^{2 m} \kappa_{2}\left(T_{i}\right)+\|S-\hat{S}\|_{2}\|\hat{R}\|_{2} \\
& \leq \frac{6 m \tilde{\gamma}_{2 n}}{1-6 m \tilde{\gamma}_{2 n}}\|A\|_{2} \prod_{i=1}^{2 m} \kappa_{2}\left(T_{i}\right)+\frac{6 m \tilde{\gamma}_{2 n}}{1-6 m \tilde{\gamma}_{2 n}} \prod_{i=1}^{2 m}\left\|T_{i}\right\|_{2}\|\hat{R}\|_{2} .
\end{aligned}
$$

From Lemma 4.8, we have

$$
\|\hat{R}\|_{2} \leq \frac{1}{1-6 m \tilde{\gamma}_{2 n}}\|A\|_{2} \prod_{i=1}^{2 m}\left\|T_{i}\right\|_{2}
$$

Since $\kappa_{2}\left(T_{i}\right)=\left\|T_{i}\right\|_{2}\left\|T_{i}^{-1}\right\|_{2}=\left\|T_{i}\right\|_{2}\left\|T_{i}^{J}\right\|_{2}=\left\|T_{i}\right\|_{2}^{2}$, the relation (4.21) is then straightforward. $\quad$ ]

REMARK 4.11.

1. The relation (4.20) gives a bound for the loss of J-orthogonality of the computed factor $\hat{S}$, and shows that $\hat{S}$ may be very close to a symplectic matrix if the optimal symplectic Householder transformations used in the process are well-conditioned.
2. The relation (4.21) gives a bound for the backward error in the factorization. This backward error may be small if the optimal symplectic Householder transformations involved in the process are well-conditioned.
3. The condition number of an optimal symplectic Householder transformation is minimal (see [13]), and this error analysis shows that their use in the SROSH algorithm constitutes the best choice.
4. Lemma 4.6 suggests a pivoting strategy for reinforcing the numerical accuracy of the algorithm.

TABLE 4.1
Residual errors in SR factors computed by SROSH for Example 4.12.

| $n$ | $\left\\|S^{J} S-I\right\\|_{2}^{\mathrm{SROSH}}$ | $\\|A-S R\\|_{2}^{\mathrm{SROSH}}$ |
| ---: | :--- | :--- |
| 8 | $1.464898 e-015$ | $1.194492 e-014$ |
| 9 | $1.464898 e-015$ | $1.749372 e-014$ |
| 10 | $1.464898 e-015$ | $3.158085 e-014$ |
| 11 | $1.464898 e-015$ | $2.842371 e-014$ |
| 12 | $1.464898 e-015$ | $6.759145 e-014$ |
| 11 | $1.464898 e-015$ | $1.149066 e-013$ |
| 12 | $1.464898 e-015$ | $2.722963 e-013$ |
| 13 | $1.464898 e-015$ | $2.692070 e-013$ |
| 14 | $1.464898 e-015$ | $4.746886 e-012$ |
| 15 | $2.031758 e-015$ | $4.711156 e-012$ |

4.3. A numerical example. To illustrate numerically the $J$-orthogonality and backward error, we consider the following example.

EXAMPLE 4.12.

$$
A=\left[\begin{array}{ll}
M_{11} & M_{12} \\
M_{21} & M_{22}
\end{array}\right]
$$

with

$$
\begin{gathered}
M_{11}=\operatorname{eye}(n) ; \\
M_{22}=\operatorname{diag}\left(e^{1 / 2}, e, \ldots, e^{n / 2}\right) ; \\
M_{12}=\left[\begin{array}{cccc}
1 \\
e^{-1} & 1 & & \\
& \ddots & \ddots & \\
& & e^{-1} & 1
\end{array}\right] ; \quad M_{21}=\left[\begin{array}{cccc}
1 & & & \\
1 & 1 & & \\
& \ddots & \ddots & \\
& & 1 & 1
\end{array}\right],
\end{gathered}
$$

where eye is the MATLAB identity function. Errors for this example are shown in Table 4.1
The second example is $A=\operatorname{rand}(2 n, 2 n)$, where rand is the MATLAB random function. Errors in this example are summarized in Table 4.2.
5. Conclusion. An error analysis of SROSH algorithm is presented. Moreover, it is showed that the loss of $J$-orthogonality of the computed symplectic factor $\hat{S}$ and the backward error of the factorization are bounded in terms of the condition number of optimal symplectic Householder transformations involved in the process. From this point of view, the free parameters as taken in optimal symplectic Householder transformations constitute the best choice. The study led us also to a pivoting strategy for increasing the accuracy of the algorithm. This will be investigated in a forthcoming paper. Computational aspects of the SROSH algorithm are studied. Storage, complexity, different implementations, factored form, block representation are discussed.

Acknowledgement. The authors are grateful to an anonymous referee for his useful comments and suggestions, which greatly improved the presentation.
