Abstract.
By means of Riccati transformation techniques we establish some oscillation criteria for the second order Emden–Fowler dynamic equation on a time scale. Such equations contain the classical Emden–Fowler equation as well as their discrete counterparts. The classical oscillation results of Atkinson (in the superlinear case) and Belohorec (in the sublinear case) are extended in this paper to Emden–Fowler dynamic equations on any time scale.

Abstract.
In this work we do a survey on the method of lower and upper solutions for periodic and anti-periodic discrete problems. Some new existence results are also given.

Key Words.

Abstract.
Results developed for the Euler–Cauchy dynamic equation are extended to a more general class of factored dynamic equations. The oscillation properties are studied in the case of isolated time scales, where a necessary and sufficient criterion for oscillation is developed.

Abstract.
We discuss factorization of the hypergeometric-type difference equations on the uniform lattices and show how one can construct a dynamical algebra, which corresponds to each of these equations. Some examples are exhibited, in particular, we show that several models of discrete harmonic oscillators, previously considered in a number of publications, can be treated in a unified form.

Abstract.
A Langenhop-type inequality is given for dynamic equations on time scales. This result is further employed to obtain lower bounds for solutions of certain dynamic equations. As an application, usage of the derived Langenhop's inequality in determining the oscillatory behavior of a damped second order delay dynamic equation is illustrated. The results obtained are important in the qualitative sense.

Abstract.
We review several methods leading to variable-coefficient schemes and/or to exact difference schemes for ordinary differential equations (error elimination; functional fitting; Principle of Coherence). Necessary and suffient conditions are given for t-independence of fitted RK coefficients. Conditions for τ-independence are investigated, τ the time-step. The theory is illustrated by examples. In particular, examples are given for non-uniqueness of exact schemes and for efficient difference schemes

based on exact schemes and well suited for highly oscillatory ordinary differential systems or for parabolic equations with blow-up solutions.

94 Pick functions related to entire functions having negative zeros. *Henrik L. Pedersen*.

Abstract.
For any sequence $\{a_k\}$ satisfying $0 < a_1 \leq a_2 \leq \ldots$ and $|a_k - k| \leq$ Const we find the Stieltjes representation of the function

$$z \mapsto \frac{\log P(z)}{z \operatorname{Log} z},$$

where P denotes the canonical product of genus 1 having $\{-a_k\}$ as its zero set.
We also find conditions on the zeros (e.g. $a_k \in [k, k+1]$ for $k \geq 1$) in order that the function

$$z \mapsto \frac{-\log P(z) + z \log P(1)}{z \operatorname{Log} z}$$

be a Pick function. We find the corresponding representation in terms of a positive density on the negative axis. We thereby generalize earlier results about the Γ-function. We also show that another related function is a Pick function.

113 Orthogonal polynomials and recurrence equations, operator equations and factorization. *Wolfram Koepf*.

Abstract.
This article surveys the classical orthogonal polynomial systems of the Hahn class, which are solutions of second-order differential, difference or q-difference equations.
Orthogonal families satisfy three-term recurrence equations. Example applications of an algorithm to determine whether a three-term recurrence equation has solutions in the Hahn class—implemented in the computer algebra system *Maple*—are given. Modifications of these families, in particular associated orthogonal systems, satisfy fourth-order operator equations. A factorization of these equations leads to a solution basis.

Abstract.
In a recent paper, Littlejohn and Wellman developed a general left-definite theory for arbitrary self-adjoint operators in a Hilbert space that are bounded below by a positive constant. We apply this theory and construct the sequences of left-definite Hilbert spaces $\{H_n\}_{n\in\mathbb{N}}$ and left-definite self-adjoint operators $\{A_n\}_{n\in\mathbb{N}}$ associated with the classical, regular self-adjoint boundary value problem consisting of the Fourier equation with periodic boundary conditions. As a particular consequence of our analysis, we obtain a Fourier expansion theorem in each left-definite space H_n as well as an explicit representation of the domain of $A^{n/2}$ for each positive integer n.

Abstract.
We study the local dynamics of maps $f(z) = -z - \sum_{n=1}^{\infty} \alpha_n z^{n+1}$, where $f(z)$ is an irreducible branch of the algebraic curve

$$z + w + \sum_{i+j=n} a_{ij} z^i w^j = 0.$$

We show that the center and cyclicity problems have simple solutions when n is odd. For the case of even n some partial results are obtained.

Abstract.
We study the Schrödinger equation for the hydrogen atom in an arbitrarily strong magnetic field in two dimensions, which is an integrable and separable system. The energy spectrum is very interesting as it has infinitely many accumulation points located at the values of the Landau energy levels of a free electron in the uniform magnetic field. In the polar coordinates the canonical (not kinetic!) angular momentum has a precise eigenvalue and we have the one dimensional radial Schrödinger equation which is an ordinary second order differential equation whose analytic exact solution is unknown. The problem is reduced to a linear three-term recurrence difference equation whose solution is unknown. We describe the qualitative properties of the energy spectrum and propose a semi-analytic method to numerically calculate the eigenenergies.
